4. Hospital efficiency

5. Improving linked dataset

# Problem: Delayed Transfers Of Care (DTOCs)

## Acute hospital stay

500,000 acute bed days lost annually just due to Social Care capacity. Costing £820m.

### Additionally:

- DTOCs propagate upstream, causing surgery cancellations, A+E crowding, and ambulance handover delays
- DTOCs affect patient outcomes, reducing physical and mental independence

# Current state of the art

## Practice

Very primitive methods in use.

Based on 'averages' and not appreciating variability in arrivals, length of stay, and discharge delays.

Such approaches are well-known to considerably underestimate capacity requirements.

## Research

There has been limited research interest in this problem.

Perhaps due to a lack of research-ready linked data across the health and care divide.

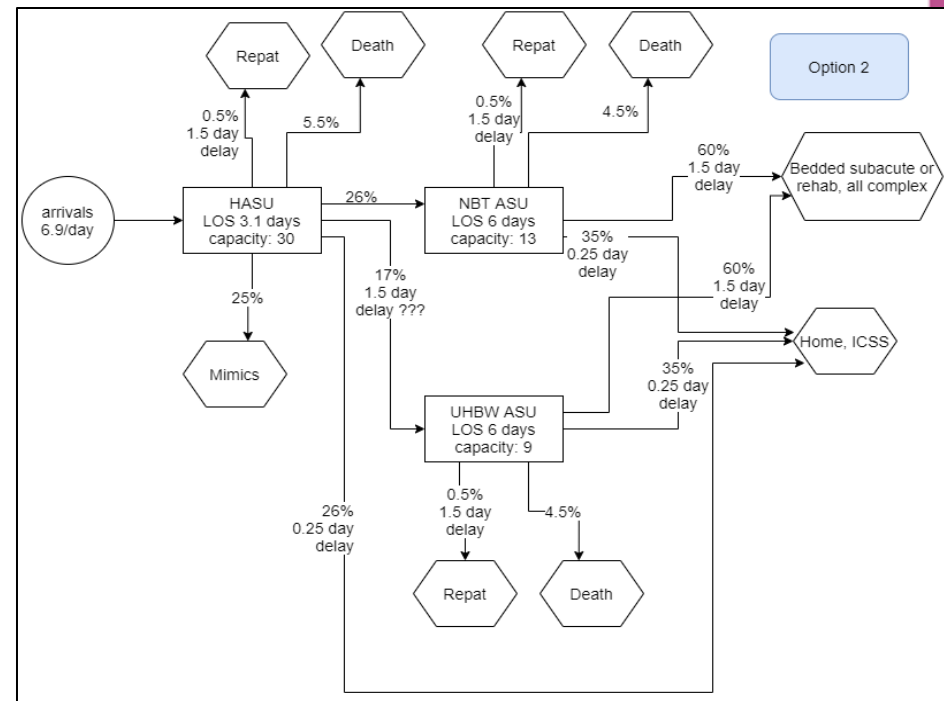

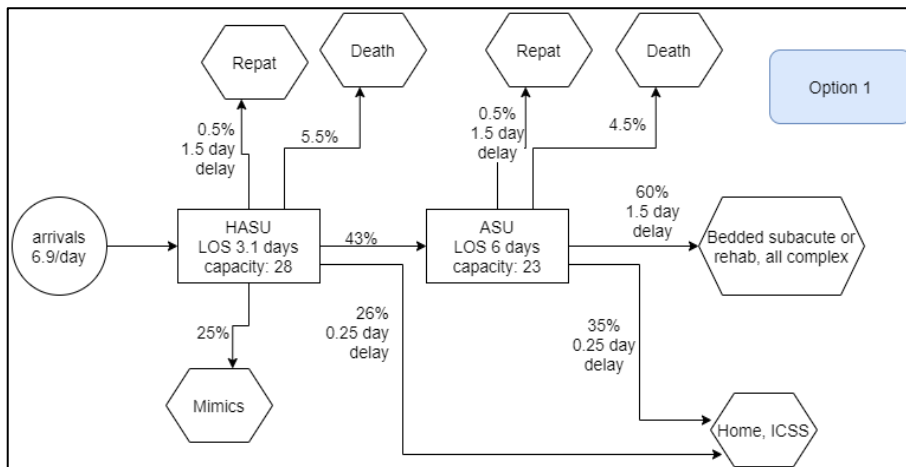

Less than a handful of potentially relevant articles could be found.

⇒ ***significant opportunity for applied research***

# Approach: Stochastic simulation of patient flow

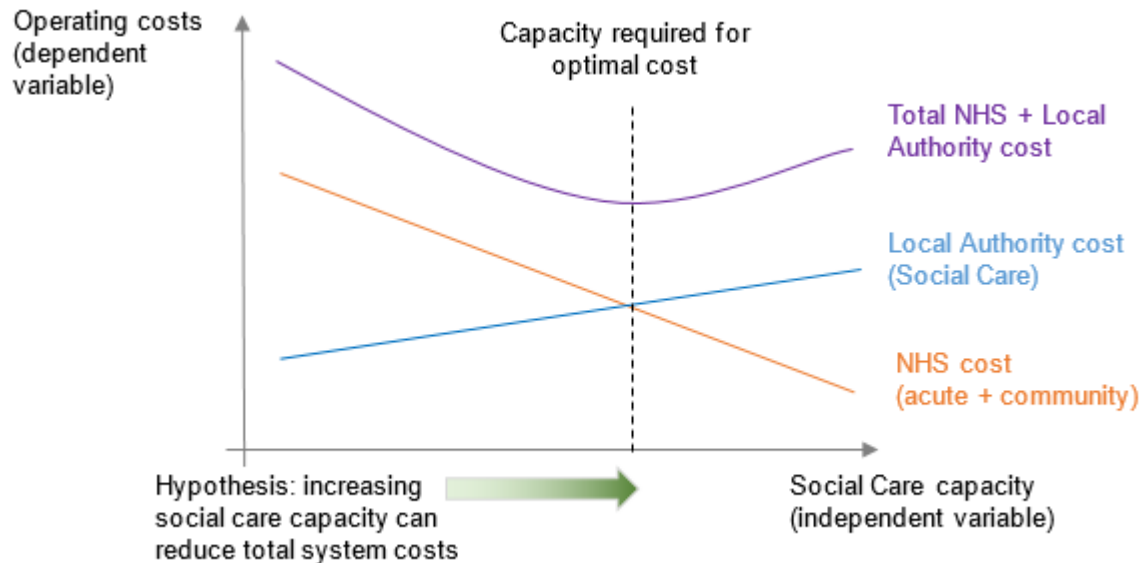

- Using queuing theory methods we will develop a dynamical model.
- Scenario analyses will be used to **optimise pathway configuration** and resources, **improving operational performance** and **patient outcomes**.

*E.g. current modelling for reconfigured centralised stroke pathway*

# Envisaged insights

- We will understand the ‘high level’ **optimal budget allocations** between health and social care.
- This will test the hypothesis that a net saving can be made by investing more in **less expensive, downstream services**.

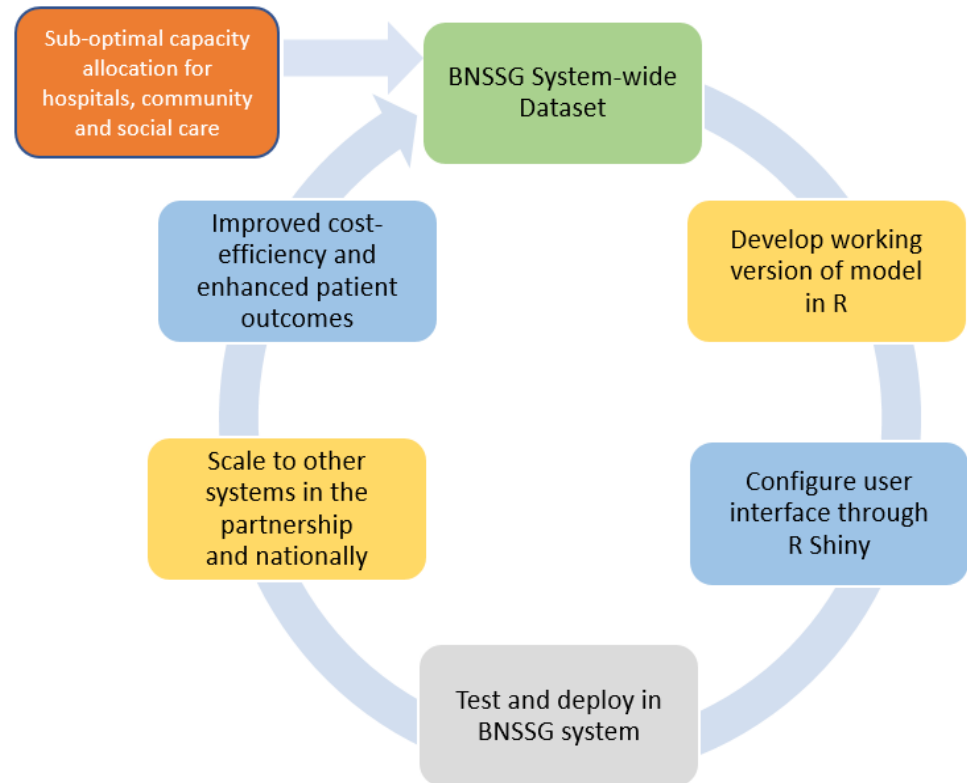

# Progress to date

- Surveyed the literature, identified others working in this space.
- Set up relationships with key people across the whole pathway.
- Reviewed various sources of data existing across the system.
- Working with analysts to sequentially improve current 'modelling' solution for operational and strategic capacity assessment.

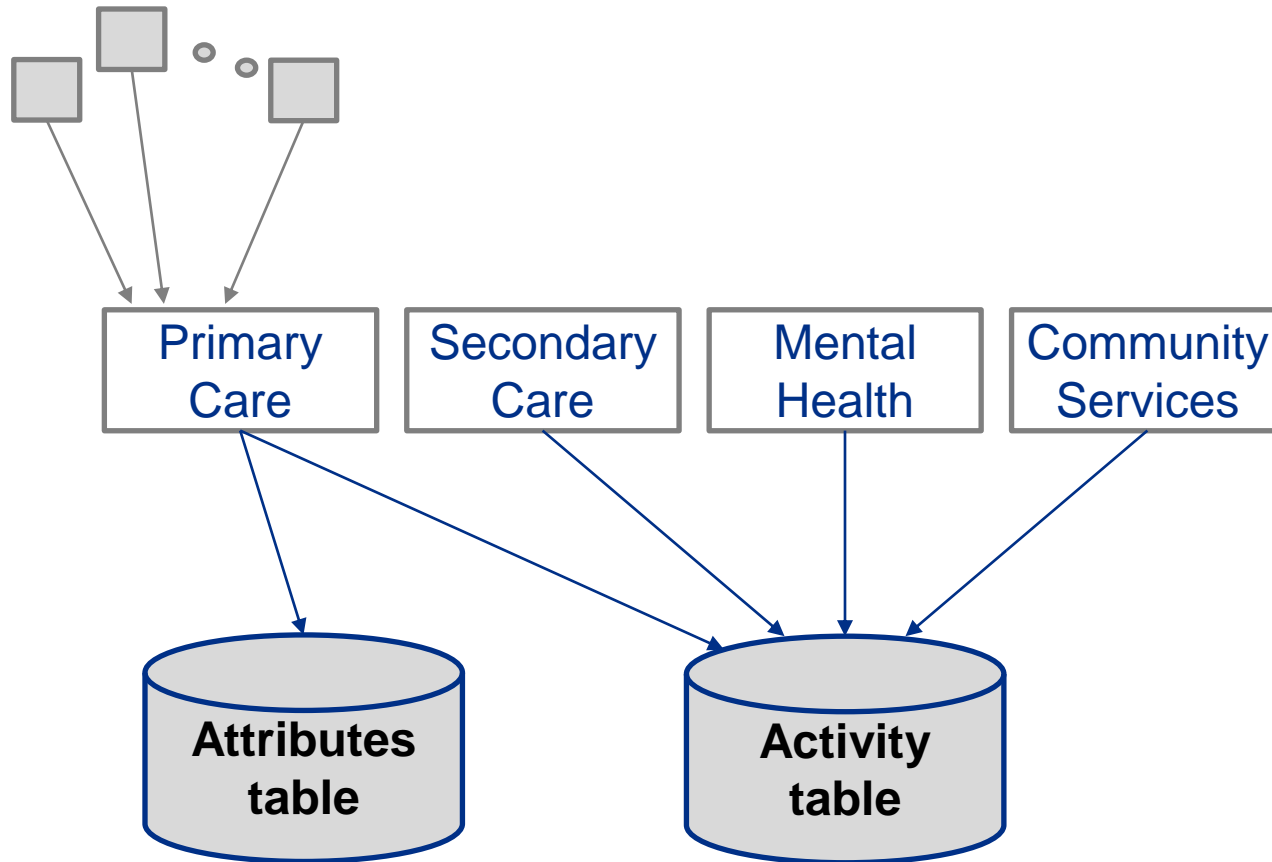

# Envisaged Better Care Loop

- We have regional partners on our bid who will work with us in **upscaling** the model and learnings across the South West.
- This is useful in ensuring sufficient **genericity** ahead of a wider release.
- Resulting interventions will be shared among healthcare systems, providing a new foundation to evolve the linked data, model, and impact.

# BNSSG System Wide Dataset @ June 2020

*x 1 million individuals*

# BNSSG SWD data structure

## Attributes table

Patient ID	Age	LTCs	...
XX1	18	0	
XX2	75	3	
XX3	34	1	
XX4	65	2	
...			

*Each row is a patient*

*Each column contains an attribute for that patient*

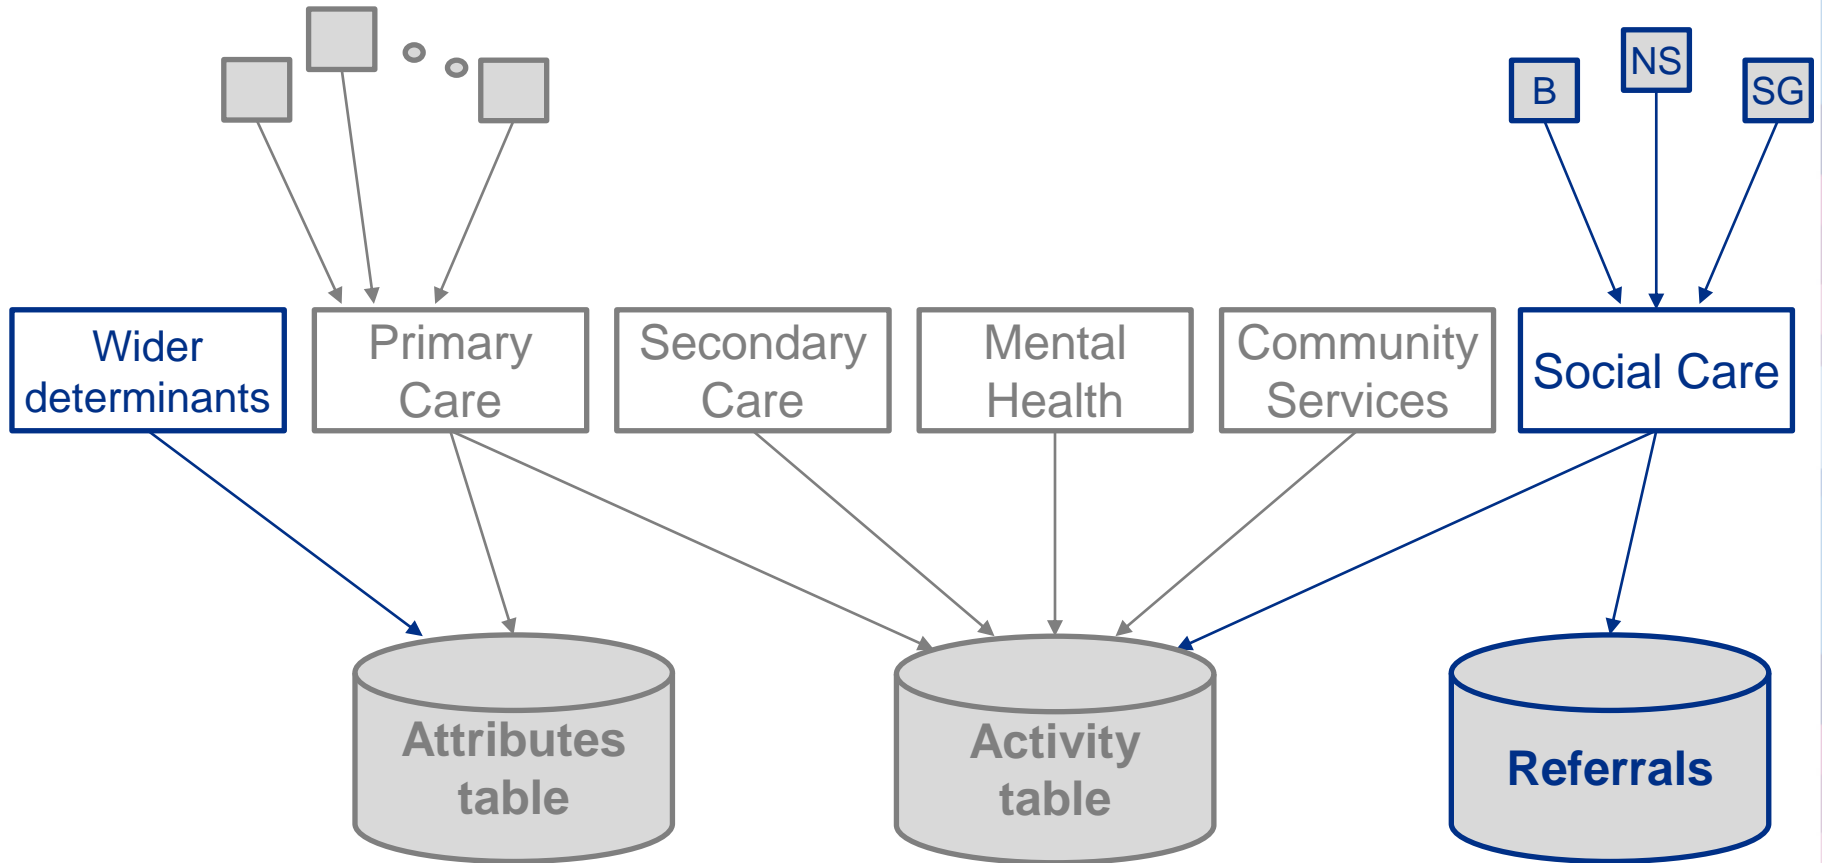

## Activity table

Patient ID	Setting	Date	...
XX1	GP appt.	04/05/19	
XX1	OP cons.	21/10/19	
XX2	A+E attend	05/07/20	
XX3	MH appt.	13/05/20	
...			

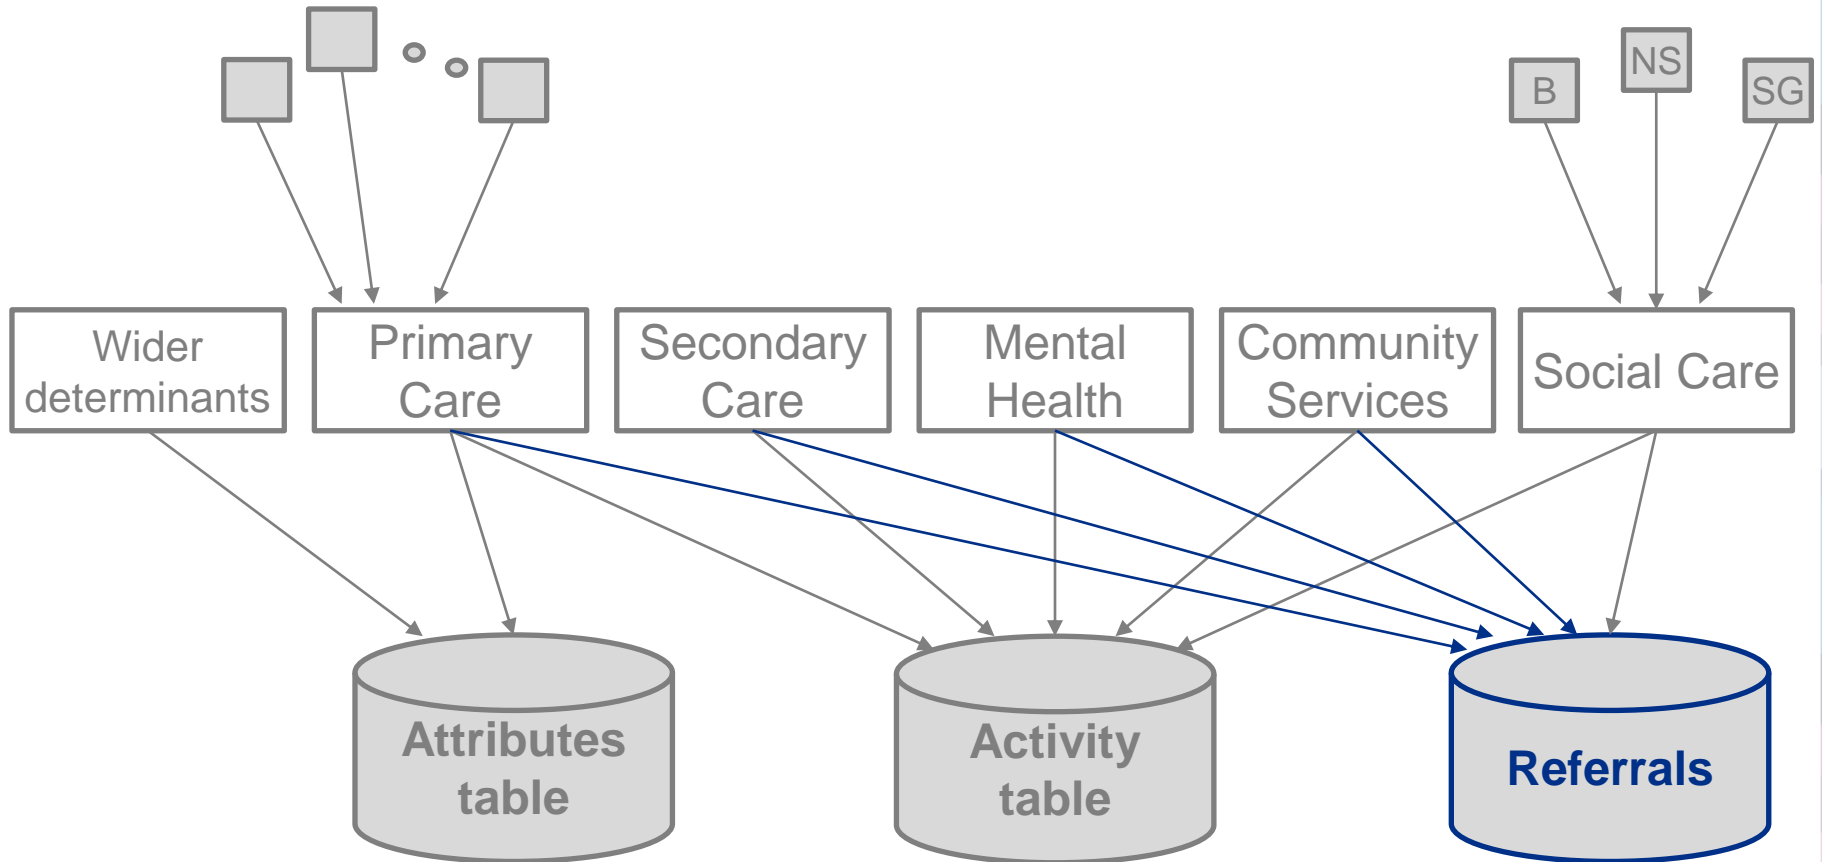

*Each row is a discrete activity*

*Each column contains details for that activity*

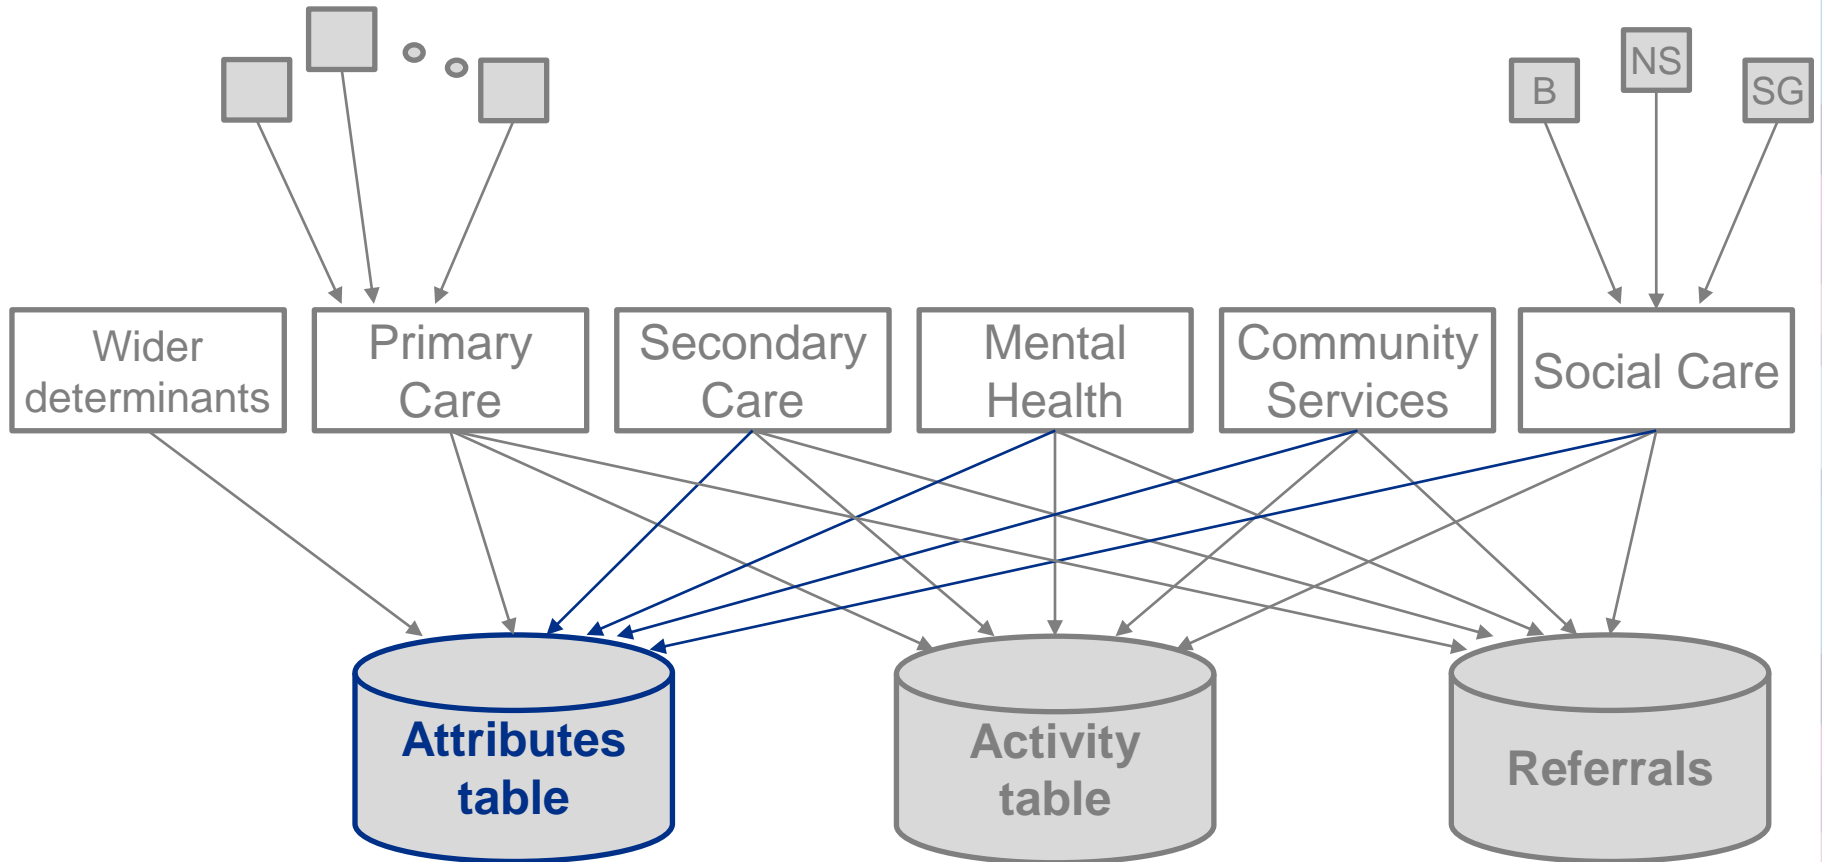

# SWD progress in recent months

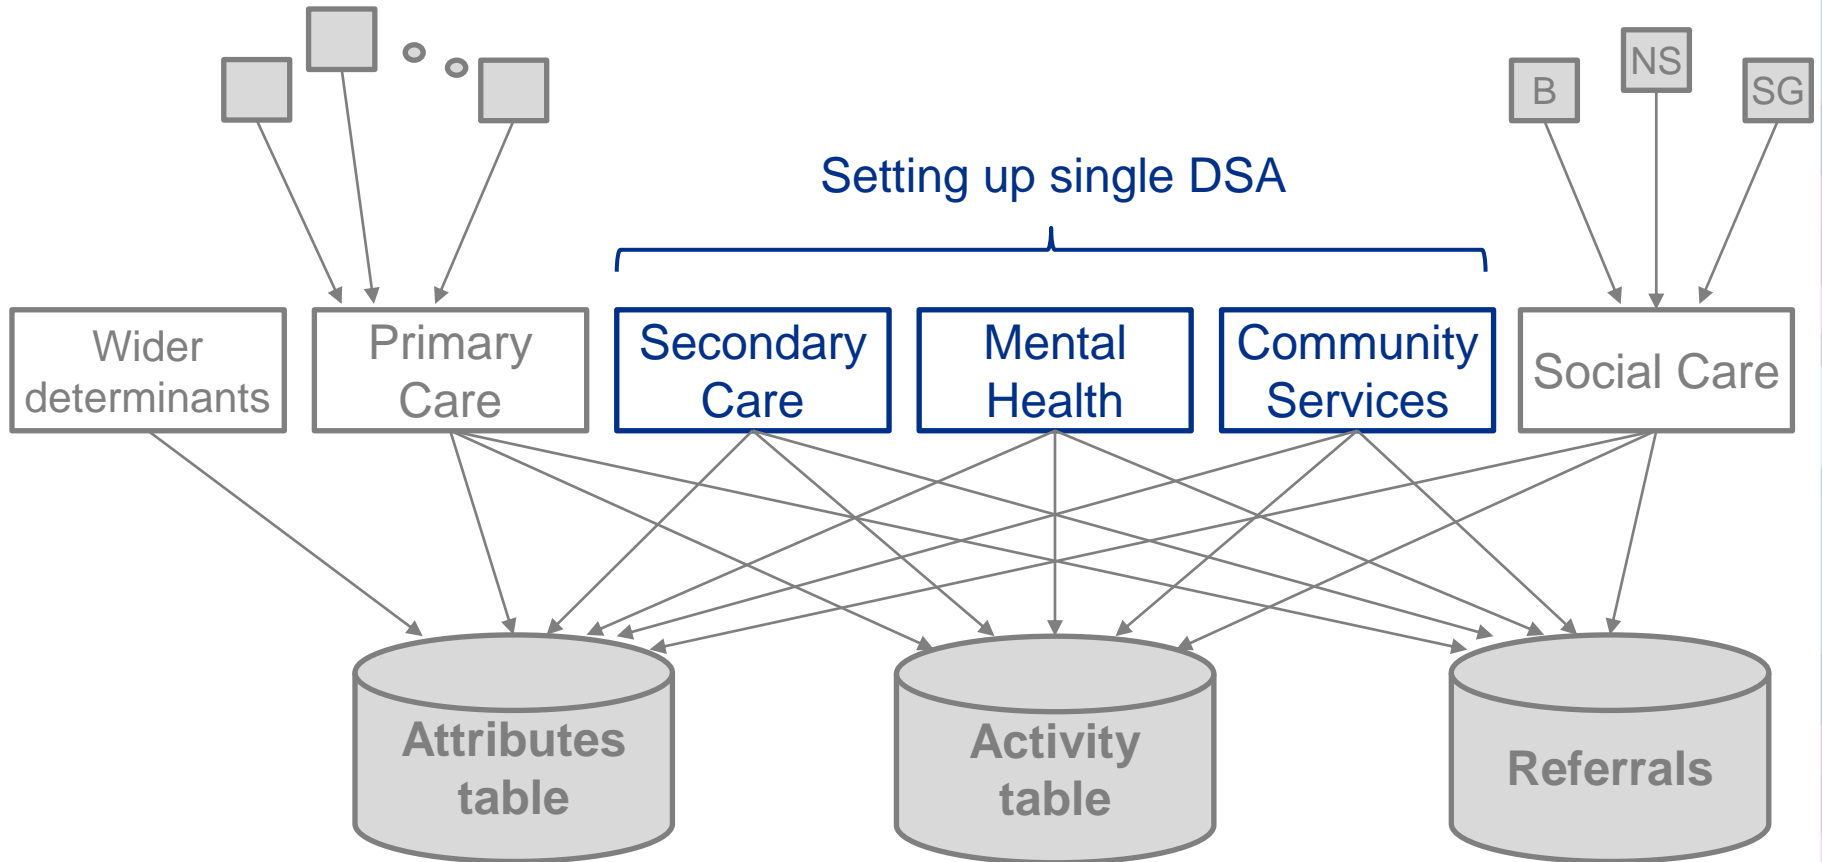

# Future plans: Enhance referrals table

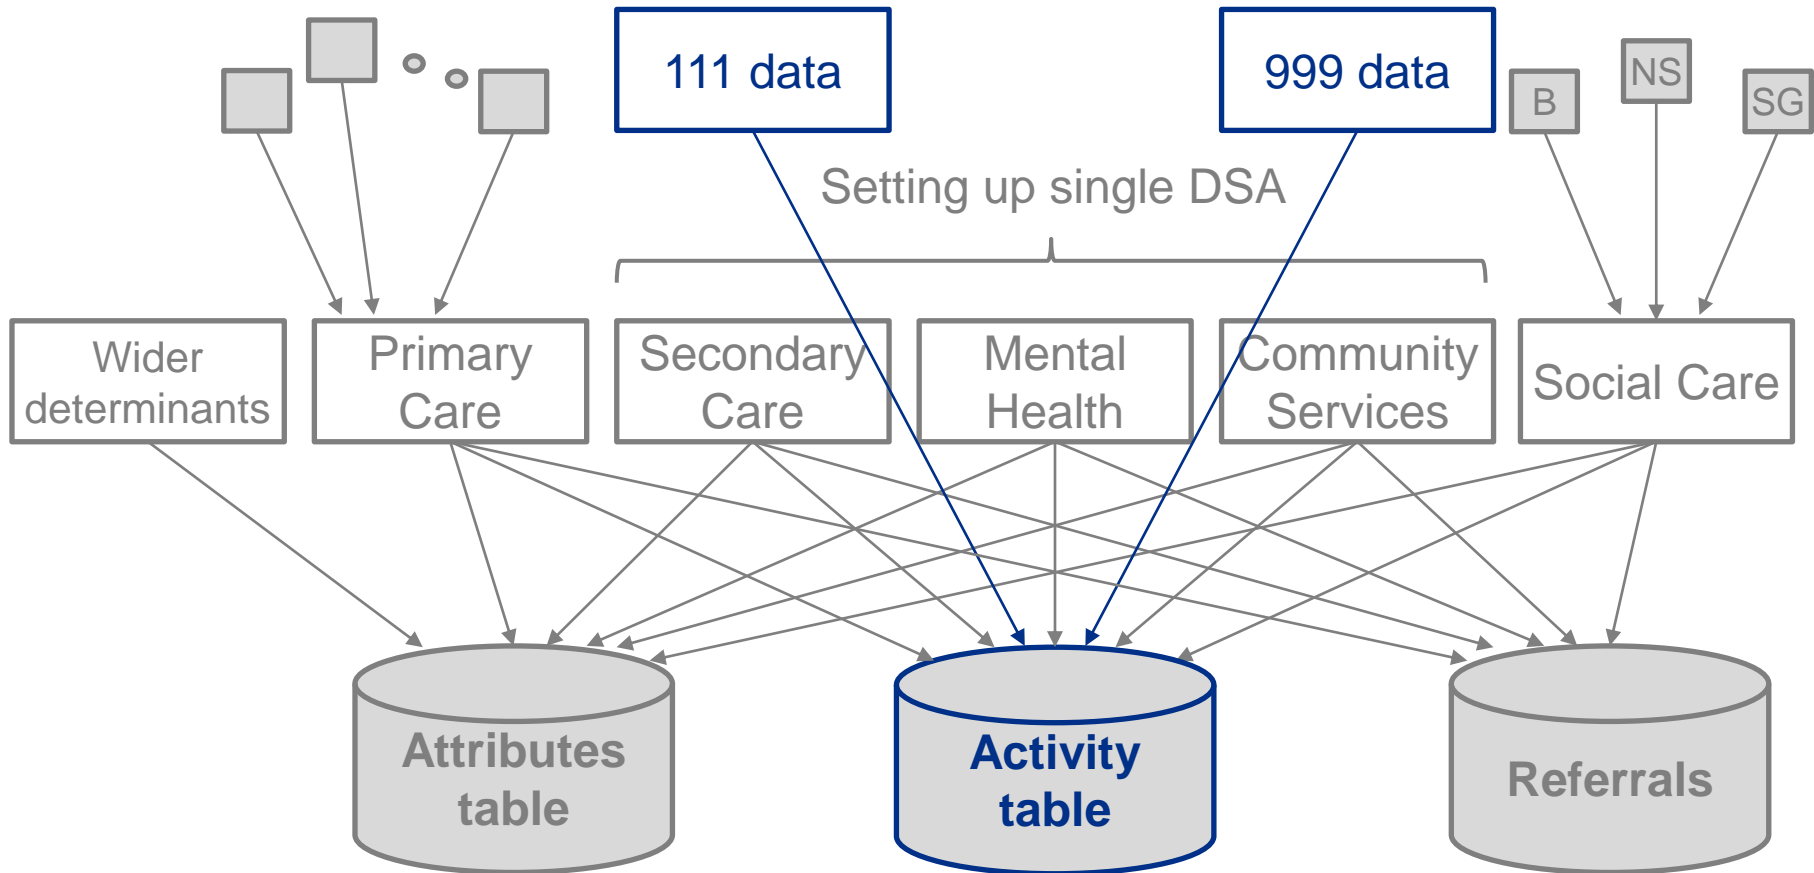

# Additional patient info into Attributes table

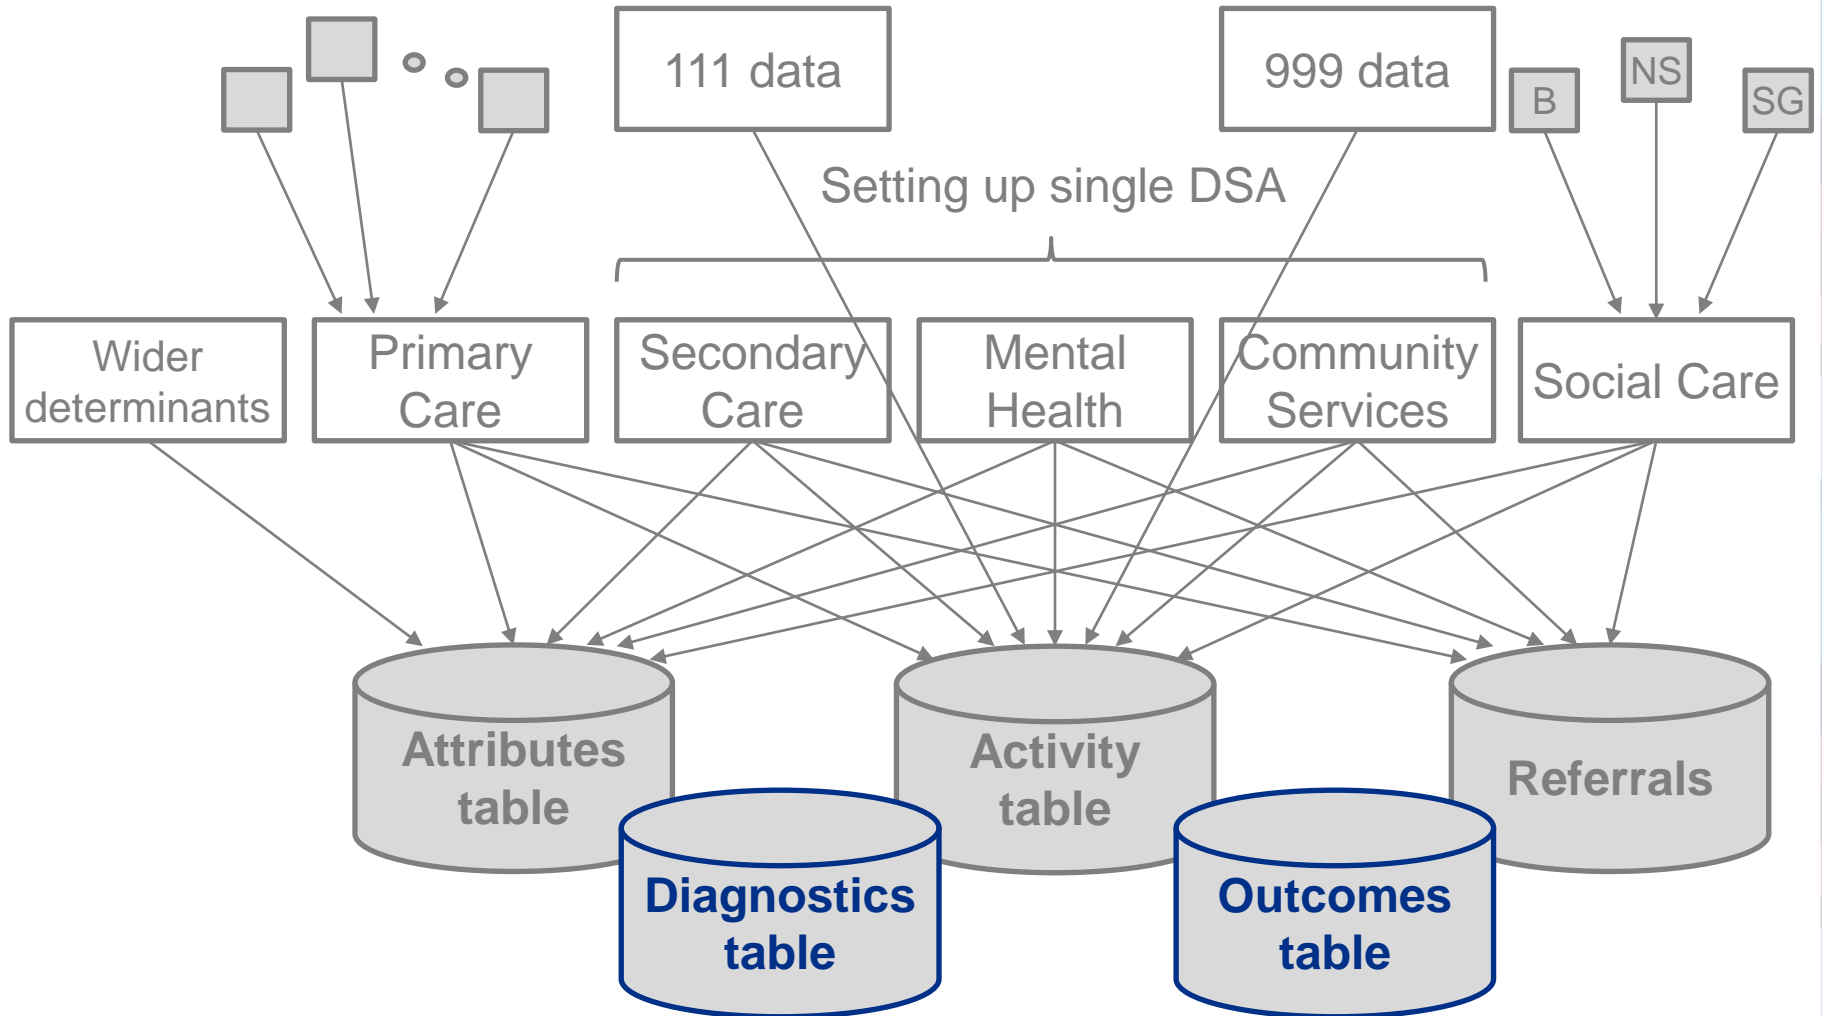

# Replace NHS-D flows with local flows

# Expand coverage of Activity table

# Bring in additional dimensions
